CHAPTER 5:

The Relational Data Model and Relational Database Constraints

Chapter Outline

- **Relational Model Concepts**
- **Relational Model Constraints and Relational Database Schemas**
- **Update Operations and Dealing with Constraint Violations**

Relational Model Concepts

- The relational Model of Data is based on the concept of a *Relation*
 - The strength of the relational approach to data management comes from the [formal foundation](#) provided by the theory of relations

Relational Model Concepts

Relational Model Concepts

- A relation is a mathematical concept based on [the ideas of sets](#)
- The model was first proposed by Dr. E.F. Codd of IBM Research in 1970 in the following paper:
 - "A Relational Model for Large Shared Data Banks," Communications of the ACM, June 1970
- The above paper caused a major revolution in the field of database management and earned Dr. Codd the coveted ACM Turing Award

Informal Definitions

- Informally, a relation looks like a table of values.
- A relation typically contains a set of rows.
- The data elements in each row represent certain facts that correspond to a real-world entity or relationship
 - In the formal model, rows are called **tuples**
- Each column has a column header that gives an indication of the meaning of the data items in that column
 - In the formal model, the column header is called an **attribute name (or just attribute)**

Example of a Relation

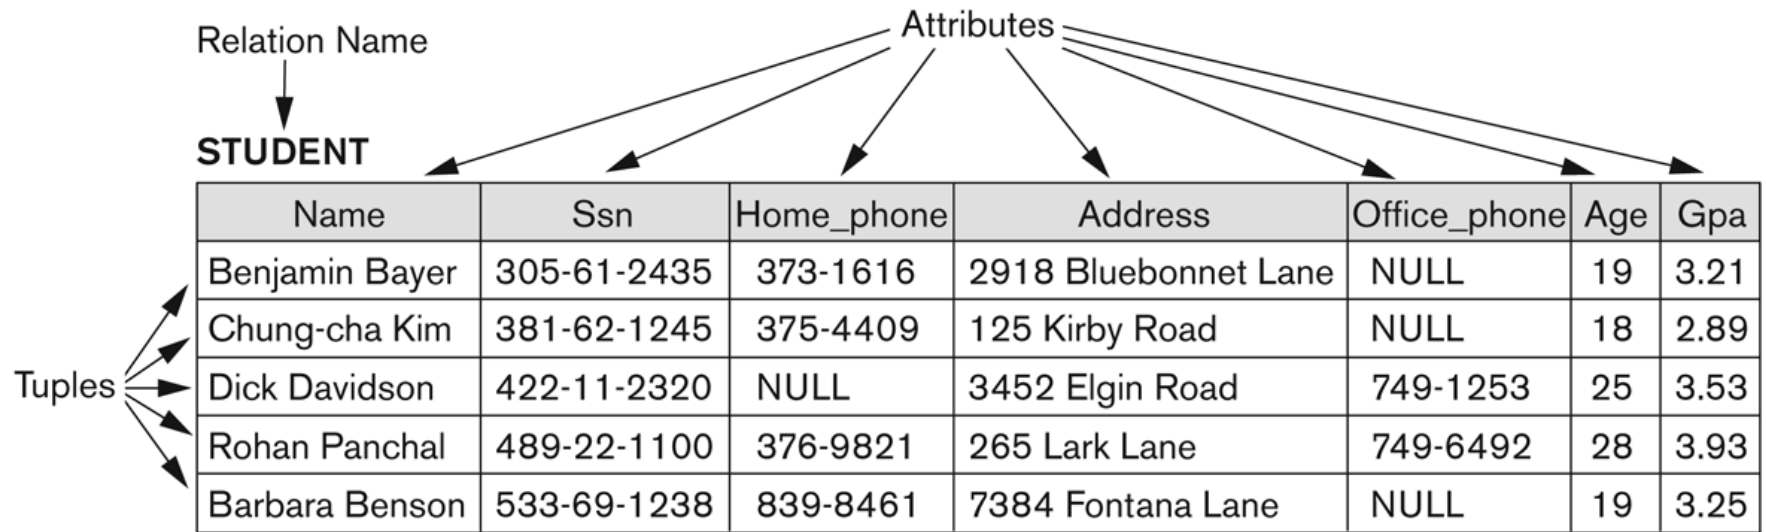

Figure 5.1

The attributes and tuples of a relation STUDENT.

Informal Definitions

- **Key of a Relation:**

- Each row has a value of a data item (or set of items) that uniquely identifies that row in the table
 - Called the *key*
- In the STUDENT table, SSN is the key
- Sometimes row-ids or sequential numbers are assigned as keys to identify the rows in a table
 - Called *artificial key or surrogate key*

Database

Model	Relational Data Model	OO Data Model
set	Relation	Object set
type	Record type or tuple type	Class
	Tuple (record)	Object
te	attribute	attribute

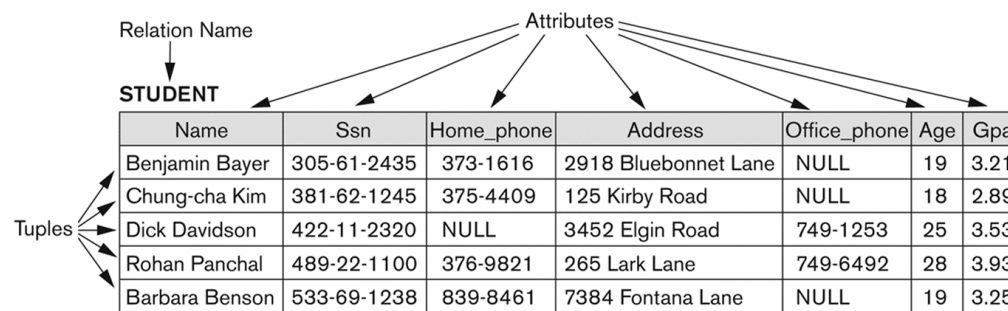

Figure 5.1

The attributes and tuples of a relation STUDENT.

Formal Definitions - Schema

- **The Schema (or description) of a Relation:**
 - Denoted by $R(A1, A2, \dots, An)$
 - R is the name of the relation
 - The attributes of the relation are A1, A2, ..., An
- **Example:**
CUSTOMER (Cust-id, Cust-name, Address, Phone#)
 - CUSTOMER is the relation name
 - Defined over the four attributes: Cust-id, Cust-name, Address, Phone#
- **Each attribute has a domain or a set of valid values.**
 - For example, the domain of Cust-id is 6 digit numbers.

Formal Definitions - Tuple

- A **tuple** is an ordered set of values (enclosed in angled brackets '**< ... >**')
 - Each value is derived from an appropriate *domain*.

CUSTOMER (Cust-id, Cust-name, Address, Phone#)

- A row in the CUSTOMER relation is a 4-tuple and would consist of four values, for example:
 - **<632895, "John Smith", "101 Main St. Atlanta, GA 30332", "(404) 894-2000">**
 - This is called a 4-tuple as it has 4 values
 - A tuple (row) in the CUSTOMER relation.
- **A relation is a set of such tuples (rows)**

Formal Definitions - Domain

- **A domain has a [logical definition](#):**
 - Example: “USA_phone_numbers” are the set of 10 digit phone numbers valid in the U.S.
- **A domain also has a [data-type](#) or [a format defined for it](#).**
 - The USA_phone_numbers may have a format: (ddd)ddd-dddd where each d is a decimal digit.
 - Dates have various formats such as year, month, date formatted as yyyy-mm-dd, or as dd mm, yyyy etc.
- **The [attribute name designates the role played by a domain in a relation](#):**
 - Used to interpret the meaning of the data elements corresponding to that attribute
 - Example: The domain Date may be used to define two attributes named “Invoice-date” and “Payment-date” with different meanings

Formal Definitions - State

- The relation state is a subset of the Cartesian product of the domains of its attributes

- each domain contains the set of all possible values the attribute can take.

$$r(R) \subseteq (\text{dom}(A_1) \times \text{dom}(A_2) \times \dots \times \text{dom}(A_n))$$

$$\text{cardinality} \longrightarrow |\text{dom}(A_1)| \times |\text{dom}(A_2)| \times \dots \times |\text{dom}(A_n)|$$

- Example: attribute **Cust-name** is defined over the domain of character strings of maximum length 25
 - $\text{dom}(\text{Cust-name})$ is `varchar(25)`
- The role these strings play in the CUSTOMER relation is that of the name of a customer.

Formal Definitions - Summary

- **Formally,**
 - Given $R(A_1, A_2, \dots, A_n)$
 $r(R) \subseteq (\text{dom}(A_1) \times \text{dom}(A_2) \times \dots \times \text{dom}(A_n))$
- $R(A_1, A_2, \dots, A_n)$ is the schema of the relation
- R is the name of the relation
- A_1, A_2, \dots, A_n are the attributes of the relation
- $r(R)$: a specific state (or "value" or "population") of relation R
 - this is a set of tuples (rows)
 - $r(R) = \{t_1, t_2, \dots, t_n\}$ where each t_i is an n -tuple
 - $t_i = \langle v_1, v_2, \dots, v_n \rangle$ where each v_j *element-of* $\text{dom}(A_j)$

Formal Definitions - Example

- Let $R(A_1, A_2)$ be a relation schema:
 - Let $\text{dom}(A_1) = \{\emptyset, 1\}$
 - Let $\text{dom}(A_2) = \{a, b, c\}$
- Then: $\text{dom}(A_1) \times \text{dom}(A_2)$ is all possible combinations:
 $\{\langle \emptyset, a \rangle, \langle \emptyset, b \rangle, \langle \emptyset, c \rangle, \langle 1, a \rangle, \langle 1, b \rangle, \langle 1, c \rangle\}$
- The relation state $r(R) \subset \text{dom}(A_1) \times \text{dom}(A_2)$
- For example: $r(R)$ could be $\{\langle \emptyset, a \rangle, \langle \emptyset, b \rangle, \langle 1, c \rangle\}$
 - this is one possible state (or “population” or “extension”) r of the relation R , defined over A_1 and A_2 .
 - It has three 2-tuples: $\langle \emptyset, a \rangle, \langle \emptyset, b \rangle, \langle 1, c \rangle$

Definition Summary

<u>Informal Terms</u>	<u>Formal Terms</u>
Table	Relation
Column Header	Attribute
All possible Column Values	Domain
Row	Tuple
Table Definition	Schema of a Relation
Populated Table	State of the Relation

Example – A relation STUDENT

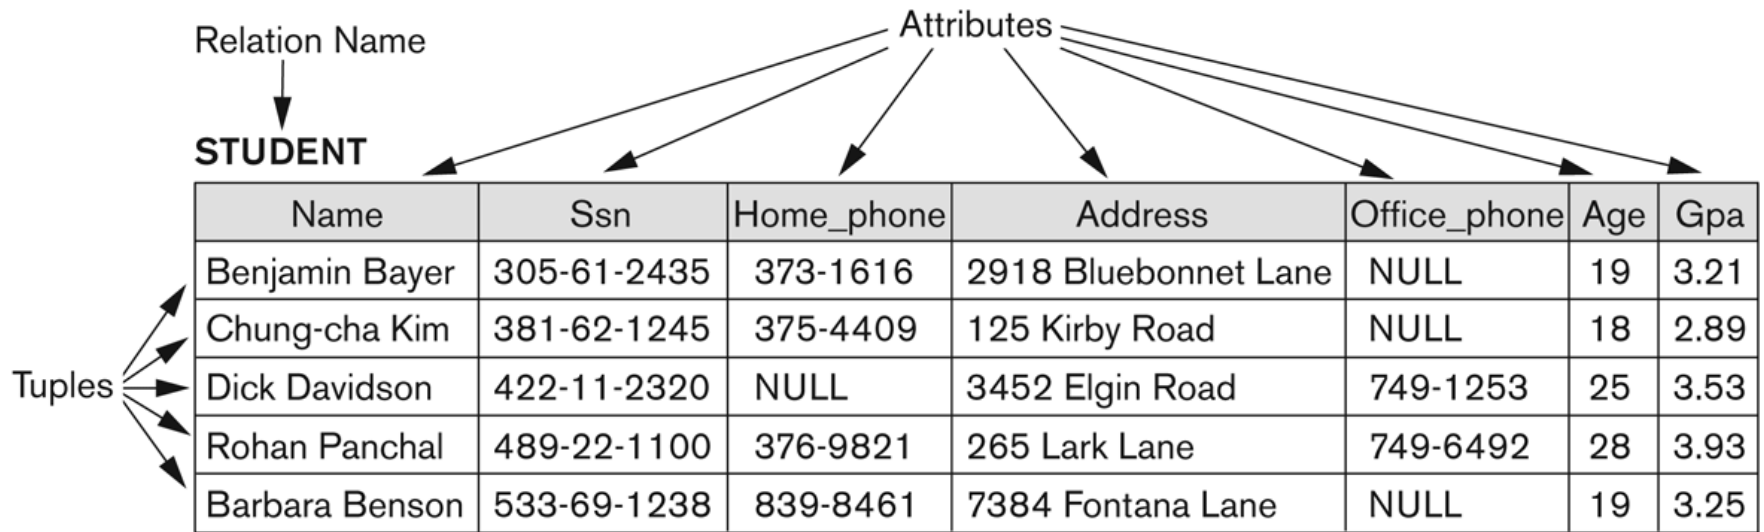

Figure 5.1

The attributes and tuples of a relation STUDENT.

Characteristics of Relations

- **Ordering of tuples in a relation $r(R)$:**
 - The tuples are not considered to be ordered, even though they appear to be in the tabular form.
- **Ordering of attributes in a relation schema R (and of values within each tuple):**
 - We will consider the attributes in $R(A_1, A_2, \dots, A_n)$ and the values in $t = \langle v_1, v_2, \dots, v_n \rangle$ to be ordered.
 - However, a more general alternative definition of relation does not require this ordering.
 - It includes both the name and the value for each of the attributes .
 - Example: $t = \{ \langle \text{name}, \text{"John"} \rangle, \langle \text{SSN}, 123456789 \rangle \}$
 - This representation may be called as "self-describing".

Same states but with different order of tuples

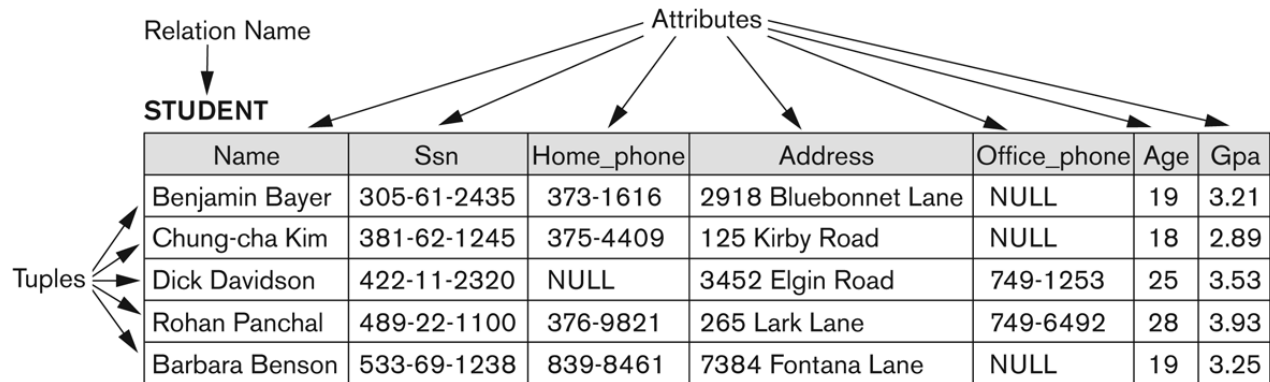

Figure 5.1

The attributes and tuples of a relation STUDENT.

Figure 5.2

The relation STUDENT from Figure 5.1 with a different order of tuples.

STUDENT

Name	Ssn	Home_phone	Address	Office_phone	Age	Gpa
Dick Davidson	422-11-2320	NULL	3452 Elgin Road	749-1253	25	3.53
Barbara Benson	533-69-1238	839-8461	7384 Fontana Lane	NULL	19	3.25
Rohan Panchal	489-22-1100	376-9821	265 Lark Lane	749-6492	28	3.93
Chung-cha Kim	381-62-1245	375-4409	125 Kirby Road	NULL	18	2.89
Benjamin Bayer	305-61-2435	373-1616	2918 Bluebonnet Lane	NULL	19	3.21

Characteristics of Relations

- **Values in a tuple:**
 - All values are considered **atomic (indivisible)**.
 - Each value in a tuple must be from the domain of the attribute for that column
 - If tuple $t = \langle v_1, v_2, \dots, v_n \rangle$ is a tuple (row) in the relation state r of $R(A_1, A_2, \dots, A_n)$
 - Then each v_i must be a value from $dom(A_i)$
 - A special **null** value is used to represent values that are **unknown** or **not available** or **inapplicable** in certain tuples.

Characteristics of Relations

- **Notation:**

$$t = \langle v_1, v_2, \dots, v_n \rangle$$

- We refer to **component values** of a tuple t by:
 - $t[A_i]$ or $t.A_i$
 - This is the value v_i of attribute A_i for tuple t
- Similarly, $t[A_u, A_v, \dots, A_w]$ refers to the subtuple of t containing the values of attributes A_u, A_v, \dots, A_w , respectively in t

Relational Model Constraints and Relational Database Schemas

CONSTRAINTS

- **Constraints** determine which values are permissible and which are not in the database.
- They are of three main types:
 1. **Inherent or Implicit Constraints:** These are based on the data model itself. (E.g., relational model does not allow a list as a value for any attribute)
 2. **Schema-based or Explicit Constraints:** They are expressed in the schema by using the facilities provided by the model. (E.g., max. cardinality ratio constraint in the ER model)
 3. **Application based or semantic constraints:** These are beyond the expressive power of the model and must be specified and enforced by the application programs.

Relational Integrity Constraints

- Constraints are conditions that must hold on all valid relation states.
- There are three *main types* of (explicit schema-based) constraints that can be expressed in the relational model:
 - **Key** constraints
 - **Entity integrity** constraints
 - **Referential integrity** constraints
- **Another schema-based constraint is the domain constraint**
 - Every value in a tuple must be from the *domain of its attribute* (or it could be **null**, if allowed for that attribute)

Key Constraints

SK = subset of attributes of R

- **Superkey of R:**
 - a set of attributes SK of R with the following condition:
 - No two tuples in any valid relation state $r(R)$ will have the same value for SK (uniqueness)
 - That is, for any distinct tuples t_1 and t_2 in $r(R)$, $t_1[SK] \neq t_2[SK]$
 - This condition must hold in any valid state $r(R)$
- **Key of R:**
 - A "minimal" superkey
 - That is, a key is a superkey K such that removal of any attribute from K results in a set of attributes that is not a superkey (does not possess the superkey uniqueness property)
- **A Key is a Superkey but not vice versa**

Key Constraints (continued)

- **Example: Consider the CAR relation schema:**
 - CAR(State, Reg#, SerialNo, Make, Model, Year)
 - CAR has two keys:
 - Key1 = {State, Reg#}
 - Key2 = {SerialNo}
 - Both are also superkeys of CAR
 - {SerialNo, Make} is a superkey but not a key.

CAR

<u>License_number</u>	Engine_serial_number	Make	Model	Year
Texas ABC-739	A69352	Ford	Mustang	02
Florida TVP-347	B43696	Oldsmobile	Cutlass	05
New York MPO-22	X83554	Oldsmobile	Delta	01
California 432-TFY	C43742	Mercedes	190-D	99
California RSK-629	Y82935	Toyota	Camry	04
Texas RSK-629	U028365	Jaguar	XJS	04

Key Constraints (continued)

- In general:
 - Any *key* is a *superkey* (but not vice versa)
 - Any set of attributes that *includes a key* is a *superkey*
 - A *minimal* superkey is also a key

CAR

<u>License_number</u>	Engine_serial_number	Make	Model	Year
Texas ABC-739	A69352	Ford	Mustang	02
Florida TVP-347	B43696	Oldsmobile	Cutlass	05
New York MPO-22	X83554	Oldsmobile	Delta	01
California 432-TFY	C43742	Mercedes	190-D	99
California RSK-629	Y82935	Toyota	Camry	04
Texas RSK-629	U028365	Jaguar	XJS	04

Key Constraints (continued)

- If a relation has several candidate keys, one is chosen arbitrarily to be the **primary key**.
 - The primary key attributes are underlined.
- **Example: Consider the CAR relation schema:**
 - CAR(State, Reg#, SerialNo, Make, Model, Year)
 - We chose SerialNo as the primary key
- The primary key value is used to **uniquely identify** each tuple in a relation
 - Provides the tuple identity
- Also used to **reference** the tuple from another tuple
 - **General rule:** Choose as primary key the smallest of the candidate keys (in terms of size)
 - Not always applicable – choice is sometimes subjective

CAR table with two candidate keys – LicenseNumber chosen as Primary Key

CAR

<u>License_number</u>	Engine_serial_number	Make	Model	Year
Texas ABC-739	A69352	Ford	Mustang	02
Florida TVP-347	B43696	Oldsmobile	Cutlass	05
New York MPO-22	X83554	Oldsmobile	Delta	01
California 432-TFY	C43742	Mercedes	190-D	99
California RSK-629	Y82935	Toyota	Camry	04
Texas RSK-629	U028365	Jaguar	XJS	04

Figure 5.4

The CAR relation, with two candidate keys: License_number and Engine_serial_number.

Relational Database Schema

- **Relational Database Schema:**
 - A set S of relation schemas that [belong to the same database](#).
 - S is the name of the whole **database schema**
 - $S = \{R_1, R_2, \dots, R_n\}$ and a set IC of integrity constraints.
 - R_1, R_2, \dots, R_n are the names of the individual **relation schemas** within the database S
- **Following slide shows a COMPANY database schema with 6 relation schemas**

COMPANY Database Schema

EMPLOYEE

the COMPANY
relational database
schema.

Relational Database State

- A relational database state DB of S is a set of relation states $DB = \{r_1, r_2, \dots, r_m\}$ such that each r_i is a state of R_i and such that the r_i relation states satisfy the integrity constraints specified in IC.
- A relational database *state* is sometimes called a relational database *snapshot* or *instance*.
- We will not use the term *instance* since it also applies to single tuples.
- A database state that does not meet the constraints is an *invalid state*

Populated database state

- Each *relation* will have many tuples in its current relation state
- The *relational database state* is a union of all the individual relation states
- Whenever the database is changed, a new state arises
- **Basic operations for changing the database:**
 - INSERT a new tuple in a relation
 - DELETE an existing tuple from a relation
 - MODIFY an attribute of an existing tuple

Populated database state for COMPANY

Entity Integrity

- **Entity Integrity:**
 - The primary key attributes PK of each relation schema R in S cannot have null values in any tuple of $r(R)$.
 - This is because primary key values are used to *identify* the individual tuples.
 - $t[PK] \neq \text{null}$ for any tuple t in $r(R)$
 - If PK has several attributes, null is not allowed in any of these attributes
 - Note: Other attributes of R may be constrained to disallow null values, even though they are not members of the primary key.

Referential Integrity

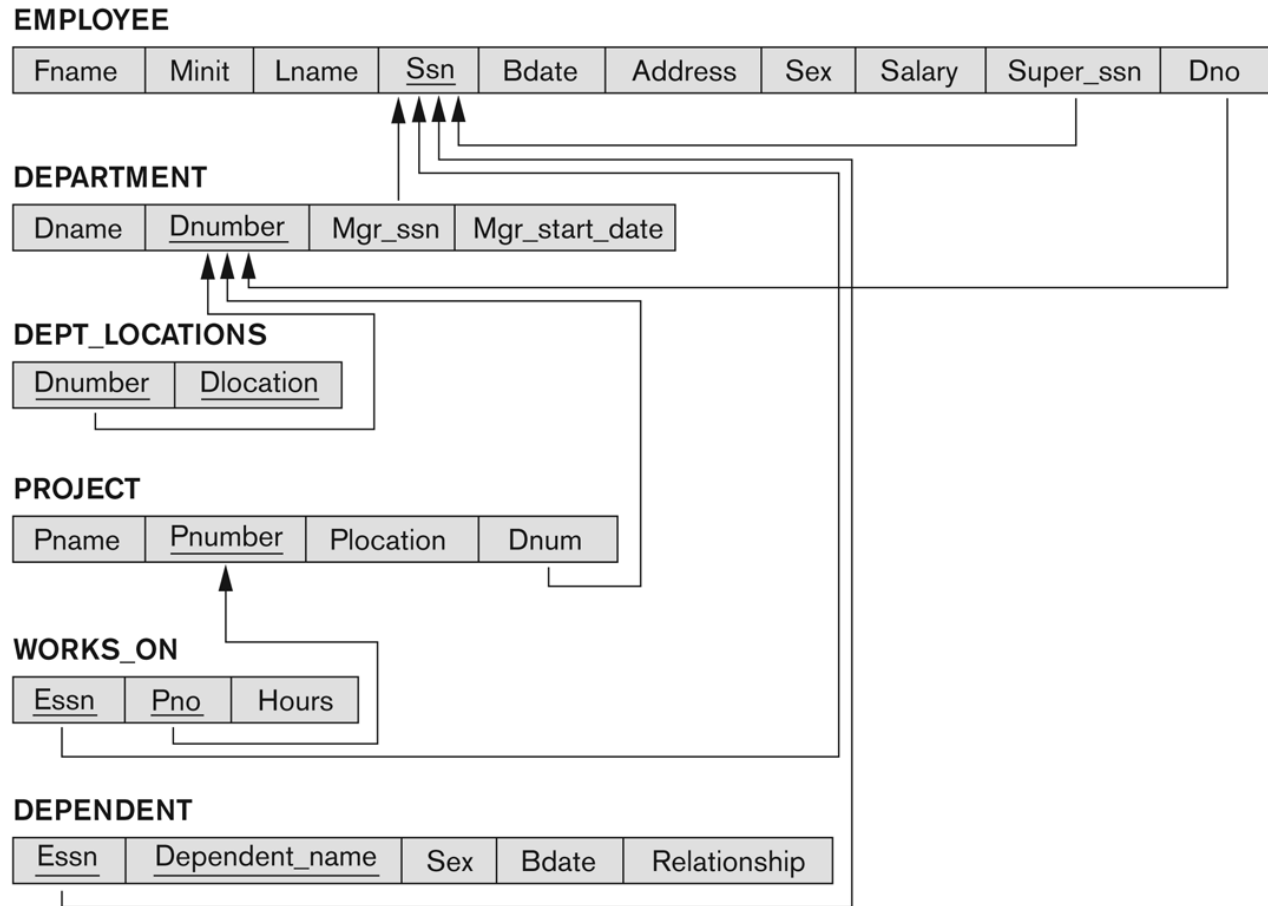

- A constraint involving two relations
 - The previous constraints involve a single relation.
- Used to specify a relationship among tuples in two relations:
 - The **referencing relation** and the **referenced relation**.

Referential Integrity

- Tuples in the **referencing relation** R1 have attributes FK (called foreign key attributes) that reference the primary key attributes PK of the referenced relation R2.
 - A tuple t_1 in R1 is said to **reference** a tuple t_2 in R2 if $t_1[\text{FK}] = t_2[\text{PK}]$.
- A referential integrity constraint can be displayed in a relational database schema as a directed arc from R1.FK to R2.

Figure 5.7

Referential integrity constraints displayed on the COMPANY relational database schema.

Referential Integrity (foreign key) Constraint

- **Statement of the constraint**
 - The value in the foreign key column (or columns) FK of the **referencing relation** R1 can be **either**:
 - (1) a value of an existing primary key value of a corresponding primary key PK in the **referenced relation** R2, or
 - (2) a **null**.
- In case (2), the FK in R1 should not be a part of its own primary key.

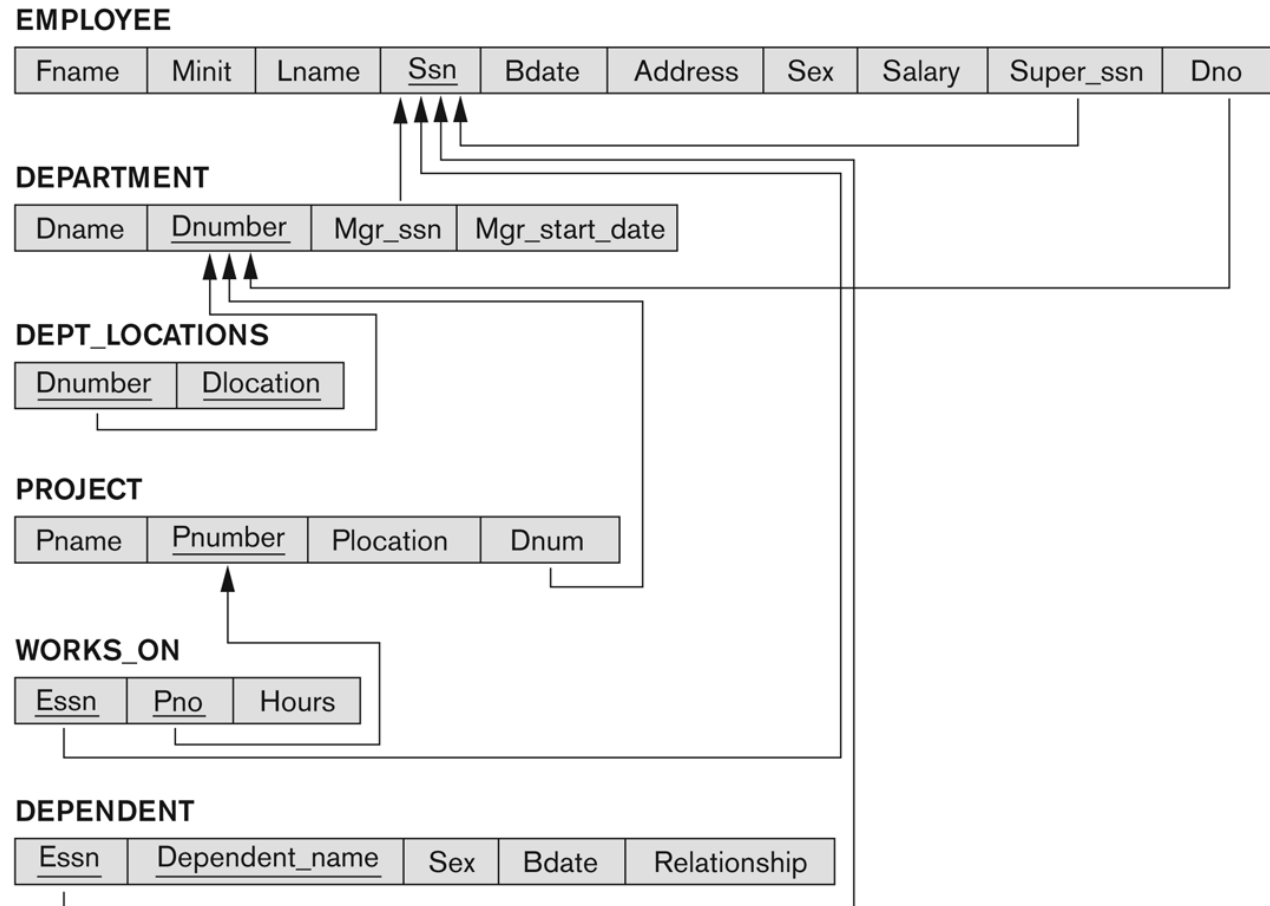

Displaying a relational database schema and its constraints

- Each relation schema can be displayed as a row of attribute names
- i.e. Student(sno, sname, address, tel, ..., dno)
- The name of the relation is written above the attribute names
- The primary key attribute (or attributes) will be underlined
- A foreign key (referential integrity) constraints is displayed as a directed arc (arrow) from the foreign key attributes to the referenced table
 - Can also point the primary key of the referenced relation for clarity
- Next slide shows the COMPANY relational schema diagram with referential integrity constraints

Referential Integrity Constraints for COMPANY database

Figure 5.7

Referential integrity constraints displayed on the COMPANY relational database schema.

Other Types of Constraints

- **Semantic Integrity Constraints:**
 - based on application semantics and cannot be expressed by the model
 - Example: "the max. no. of hours per employee for all projects he or she works on is 56 hours per week"
- **A constraint specification language may have to be used to express these**
- **SQL-99 allows CREATE TRIGGER and CREATE ASSERTION to express some of these semantic constraints**
- **Keys, Permissibility of Null values, Candidate Keys (Unique in SQL), Foreign Keys, Referential Integrity etc. are expressed by the CREATE TABLE/ALTER TABLE statement in SQL.**

Update Operations, Transactions, and Dealing with Constraint Violations

Update Operations on Relations

- **INSERT a tuple.**
- **DELETE a tuple.**
- **MODIFY a tuple.**
- **Integrity constraints** should not be violated by the update operations.
- Several update operations may have to be grouped together.
- Updates may propagate to cause other updates automatically.
This may be necessary to maintain integrity constraints.

Update Operations on Relations

- In case of integrity violation, several actions can be taken:
 - Cancel the operation that causes the violation (RESTRICT or REJECT option)
 - Perform the operation but inform the user of the violation
 - **Trigger additional updates** so the violation is corrected (CASCADE option, SET NULL option)
 - Execute a user-specified error-correction routine

Possible violations for each operation

- **INSERT** may violate any of the constraints:
 - **Domain constraint:**
 - if one of the attribute values provided for the new tuple is not of the specified attribute domain
 - **Key constraint:**
 - if the value of a key attribute in the new tuple already exists in another tuple in the relation
 - **Referential integrity:**
 - if a foreign key value in the new tuple references a primary key value that does not exist in the referenced relation
 - **Entity integrity:**
 - if the primary key value is null in the new tuple

Possible violations for each operation

- **DELETE** may violate only referential integrity:
 - If the primary key value of the tuple being deleted is referenced from other tuples in the database
 - Can be remedied by several actions: RESTRICT, CASCADE, SET NULL
 - **RESTRICT** option: reject the deletion
 - **CASCADE** option: propagate the new primary key value into the foreign keys of the referencing tuples
 - **SET NULL** option: set the foreign keys of the referencing tuples to NULL
 - One of the above options must be specified during database design for each foreign key constraint

Possible violations for each operation

- **UPDATE** may violate domain constraint and NOT NULL constraint on an attribute being modified
- **Any of the other constraints may also be violated, depending on the attribute being updated:**
 - Updating the primary key (PK):
 - Similar to a DELETE followed by an INSERT
 - Need to specify similar options to DELETE
 - Updating a foreign key (FK):
 - May violate referential integrity
 - Updating an ordinary attribute (neither PK nor FK):
 - Can only violate domain constraints

Summary

- **Presented Relational Model Concepts**
 - Definitions
 - Characteristics of relations
- **Discussed Relational Model Constraints and Relational Database Schemas**
 - Key constraints
 - Entity integrity
 - Referential integrity
 - Domain constraints
- **Described the Relational Update Operations and Dealing with Constraint Violations**

In-Class Exercise

Consider the following relations for a database that keeps track of student enrollment in courses and the books adopted for each course:

STUDENT(SSN, Name, Major, Bdate)

COURSE(Course#, Cname, Dept)

ENROLL(SSN, Course#, Quarter, Grade)

BOOK_ADOPTION(Course#, Quarter, Book_ISBN)

TEXT(Book_ISBN, Book_Title, Publisher, Author)

Draw a relational schema diagram specifying the foreign keys for this schema.
